

① We know that:

$$P(R|A) = 0.99$$

$$P(R|\text{not } A) = 0.1$$

$$P(A) = 0.05, \text{ so } P(\text{not } A) = 0.95$$

By Bayes' Rule,

$$P(A|R) = \frac{P(A) \cdot P(R|A)}{P(R)}$$

Moreover, using the Rule of Total Probability,

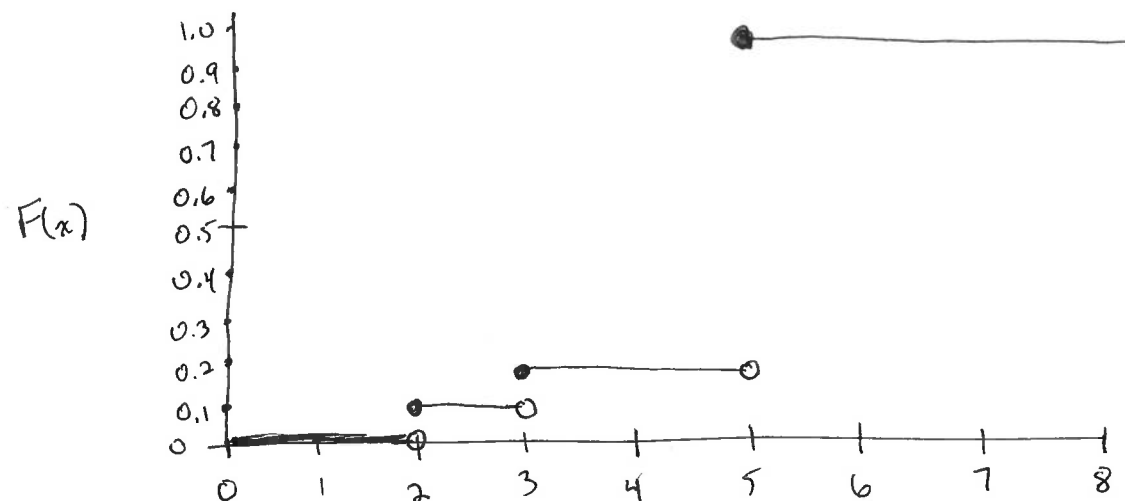

$$\begin{aligned} P(R) &= P(R|A) \cdot P(A) + P(R|\text{not } A) \cdot P(\text{not } A) \\ &= 0.99 \cdot 0.05 + 0.1 \cdot 0.95 \end{aligned}$$

$$\text{So } P(A|R) = \frac{0.05 \times 0.99}{0.99 \times 0.05 + 0.1 \times 0.95}$$

(This expression is enough, but the number turns out to be
 $P(A|R) \approx 0.343$)

② X has PMF $f(x) = \begin{cases} 1/10 & \text{if } x=2 \\ 1/10 & \text{if } x=3 \\ 8/10 & \text{if } x=5 \end{cases}$

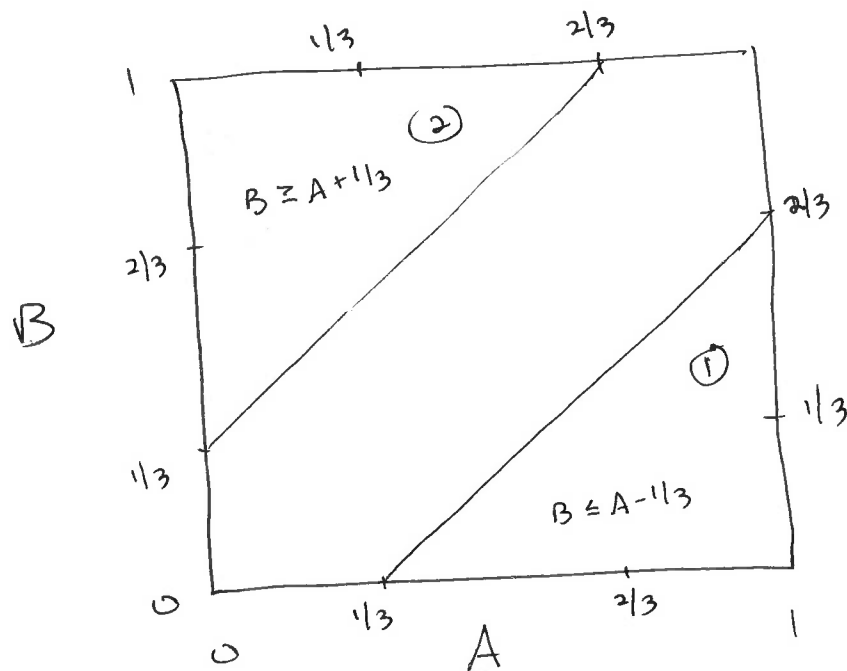

The CDF looks like the following picture

$$\begin{aligned} P(2 < X \leq 4.5) &= P(\{x : x \in (2, 4.5]\}) \\ &= P(X=3), \text{ since } x=3 \text{ is the only possible value of } x \text{ that falls in } (2, 4.5]. \\ &= 1/10 \end{aligned}$$

$$\begin{aligned} P(2 \leq X \leq 4.5) &= P(X=2) + P(X=3) \\ &= \frac{1}{10} + \frac{1}{10} = \frac{2}{10} \end{aligned}$$

- ③ Let A be Alice's delay in hours, and let B be Bob's delay in hours. If all possible pairs of delays are likely, then A and B are uniformly distributed over the following rectangle:

Alice and Bob will miss each other if $|A - B| \geq 1/3$, since each will wait for a maximum of $1/3$ of an hour. And:

$$\begin{aligned}
 P(|A - B| \geq 1/3) &= P(A - B \geq 1/3) + P(A - B \leq -1/3) \\
 &= P(B \leq A - 1/3) + P(B \geq A + 1/3) \\
 &= \text{Area of triangle 1} + \text{Area of triangle 2} \\
 &= \frac{2}{3} \cdot \frac{2}{3} \cdot \frac{1}{2} + \frac{2}{3} \cdot \frac{2}{3} \cdot \frac{1}{2} \\
 &= \frac{4}{9}
 \end{aligned}$$

$$\text{So } p(\text{meet}) = 1 - 4/9 = 5/9$$

④ Markov's argument is wrong; we can't calculate

$$E(T) = E\left(\frac{2}{v}\right) \neq \frac{2}{E(v)}$$

In general, $E(f(x)) \neq f(E(x))$

Instead, to calculate $E(T)$, note that there are two possibilities:

- If he walks, $T = \frac{2 \text{ miles}}{5 \text{ miles/hour}} = \frac{2}{5} \text{ hour}$

- If he rides, $T = \frac{2 \text{ miles}}{10 \text{ miles/hour}} = \frac{2}{10} \text{ hour}$

$$\text{Therefore, } E(T) = 0.4 \times \frac{2}{5} + 0.6 \times \frac{2}{10}$$

(This expression is enough, but the final value turns out to be $\frac{4}{10} \cdot \frac{4}{10} + \frac{6}{10} \times \frac{2}{10} = \frac{16}{100} + \frac{12}{100} = \frac{28}{100} \text{ hours} \approx 16.8 \text{ minutes}$ (not 15))

5) Part B

$$Y_n = \max \{X_1, \dots, X_N\}$$

To find the PDF $f(y)$, first find the CDF.

$$F(y) = P(Y_n \leq y) = P(\max \{X_1, \dots, X_n\} \leq y)$$

$$\text{But } \max \{X_1, \dots, X_N\} \leq y \iff X_i \leq y \text{ for all } i=1, \dots, N$$

(hint)

$$\text{So } P(Y_n \leq y) = P(X_1 \leq y, X_2 \leq y, \dots, X_n \leq y)$$

$$= \prod_{i=1}^N P(X_i \leq y) \quad \text{By independence.}$$

$$= \prod_{i=1}^N [1 - e^{-\lambda y}] \quad \text{By the given integral.}$$

$$= [1 - e^{-\lambda y}]^N$$

$$\text{Therefore } \underbrace{f(y) = F'(y)} = \underbrace{N [1 - e^{-\lambda y}]^{N-1}} \lambda e^{-\lambda y}$$

This is the
important thing to
recognize

It didn't matter
whether you remembered
how to take this
derivative by hand.
